

## Declaration of CryoClim product compliance with the

### GCOS climate monitoring principles

### for the GST product provided by NPI

**Latest update of document: 25 October 2013**

The Global Climate Observing System (GCOS) provides recommendations for satellite-based observations of the climate in support of the United Nations Framework Convention on Climate Change (UNFCCC) (see GCOS report no. 107, Systematic observation requirements for satellite-based products for climate). The ten basic principles were adopted by the Conference of the Parties (COP) to UNFCCC through decision 5/CP.5 at COP-5 in November 1999. The complete set of 20 principles was adopted by COP through decision 11/CP.9 at COP-9 in December 2003.

The CryoClim service aims at adhering to the climate monitoring principles as far as practical feasible. To assist the provision of information to users about the current level of adherence to the principles for each product type, this compliance declaration is provided and updated following algorithm updates and other changes affecting the product content and quality.

GCOS' principles no. 11–20 are specific to satellite-based systems for climate monitoring. The principles are provided below together with statements on CryoClim product adherence:

*11. Constant sampling within the diurnal cycle (minimizing the effects of orbital decay and orbit drift) should be maintained.*

C-band SAR images are used where available but usually cover all times of the day.

*12. A suitable period of overlap for new and old satellite systems should be ensured for a period adequate to determine inter-satellite biases and maintain the homogeneity and consistency of time-series observations.*

The launch of Sentinel-1 is expected to give an overlap to Radarsat. Overlaps between ERS-1, ERS-2 and ENVISAT ASAR exist in the time series

*13. Continuity of satellite measurements (i.e. elimination of gaps in the long-term record) through appropriate launch and orbital strategies should be ensured.*

C-band SAR data have been continuously available from satellites since 1991, and further continuity is expected through the operational Sentinel-1 satellites and the Radarsat satellites.

*14. Rigorous pre-launch instrument characterization and calibration, including radiance confirmation against an international radiance scale provided by a national metrology institute, should be ensured.*

This is carried out for the sensors used (ERS-1, ERS-2, ENVISAT ASAR, Radarsat-1 and Radarsat-2) and in the future for Sentinel-1 and Radarsat Constellation.

*15. On-board calibration adequate for climate system observations should be ensured and associated instrument characteristics monitored.*

This has been done for the ENVISAR ASAR and will be done for Sentinel-1.

*16. Operational production of priority climate products should be sustained and peer reviewed new products should be introduced as appropriate.*

The CryoClim Svalbard sub-service is operated operationally by NPI with sustained funding. This includes R&D leading to new and improved products as new algorithms and sensors become available.

*17. Data systems needed to facilitate user access to climate products, metadata and raw data, including key data for delayed-mode analysis, should be established and maintained.*

The CryoClim System as well as the Norwegian Polar Institute's Data Centre will be maintained.

*18. Use of functioning baseline instruments that meet the calibration and stability requirements stated above should be maintained for as long as possible, even when these exist on de-commissioned satellites.*

Currently not applicable

*19. Complementary in situ baseline observations for satellite measurements should be maintained through appropriate activities and cooperation.*

Glaciological field work will continue and is supporting satellite measurements.

*20. Random errors and time-dependent biases in satellite observations and derived products should be identified.*

Such effects are expected to be studied in the future as the time series becomes longer.
